**Abstract---Background:** The integration of Electronic Medical Records (EMRs) in healthcare systems has revolutionized the management of patient information, enhancing efficiency and accessibility. This study explores the impact of EMRs on Clinical Safety Indicator (CSI) behavior among healthcare professionals, focusing on doctors and nurses, who play crucial roles in medical record creation and utilization. **Methods:** A comprehensive literature review was conducted to assess the prevalence of EMR usage, perceived benefits, concerns, and attitudes toward digital record-keeping. Data was collected to understand the relationship between EMR adoption, professional roles, and perceptions of data security and integrity. **Results:** Findings revealed a higher inclination of doctors towards EMR adoption compared to nurses, with concerns shared by both groups regarding data accessibility, reliability, and comprehensibility. Nurses tended to prefer traditional paper records, impacting their engagement with EMRs. Security and privacy concerns surrounding EMRs were highlighted, influencing professionals' trust in Health Information Systems (HIS) and data privacy safeguards. **Conclusion:** The study underscores the importance of addressing healthcare professionals' attitudes and concerns toward EMRs to enhance their integration and utilization. Improved training on digital healthcare systems and addressing data security issues are crucial for promoting EMR adoption and ensuring effective communication and collaboration among healthcare teams. Future research should focus on mitigating barriers to EMR use and enhancing trust in digital healthcare technologies.

**Keywords---**Electronic Medical Records, Clinical Safety Indicators, Healthcare Professionals, Data Security, Digital Healthcare.

## 1. Introduction

Digitalization, characterized as “the real-time collection, analysis, and application of digital data for specific objectives”, is linked to enhanced efficiency, greater accessibility, and optimized resource utilization [1, 2]. The advancement of health information systems alongside the evolution of information and communication technologies, the necessity to assess health services comprehensively, and the COVID-19 pandemic revealing pre-existing obstacles in accessing medical records have expedited the development of digital hospital services (DHS) [3-5].

The Hospital Information System (HIS) is used to monitor patient status within healthcare organizations, maintain health records, and archive historical data for

further diagnosis, providing multi-center and multi-user access for the preservation and utilization of electronic medical records (EMRs) [6,7]. As the significance of information in corporate performance escalates, the emphasis on knowledge sharing as a mechanism for success and competitive advantage correspondingly intensifies [8]. Originally used for recordkeeping, EMRs are becoming more vital for the dissemination of medical information essential for the efficient provision of healthcare services, provided that access, quality, and security standards are satisfied within the DHS [9].

Electronic Medical Records (EMR), generated through the electronic documentation of routine procedures such as laboratory tests, imaging, nursing, billing, and pharmacology, about diagnostic and therapeutic activities within healthcare organizations or through manual data entry, constitute a fundamental element of the Digital Health System (DHS) [10-14]. Created across various departments, at disparate times, and by diverse healthcare professionals, EMRs facilitate multi-center and multi-user access to the storage and utilization of health records, significantly contributing to the delivery of treatment services, patient follow-up, and remote management of chronic conditions; disease detection and classification; enhancement of clinical decision-making; and the optimization of healthcare service efficiency [15].

Electronic Medical Records (EMR) facilitate integration among healthcare professionals and organizations by ensuring continuous documentation of data generated during treatment and adherence to standards [16-19]. They support health platforms, including telemedicine and e-health, by establishing a medical database. It minimizes expenses by optimizing resource use, mitigates waste, and enhances happiness among patients and employees [20-25]. Simultaneously, it establishes a legal safety net by documenting treatment and care services, providing legal protection for patients, healthcare professionals, and healthcare institutions as stakeholders in healthcare services.

Altering health practices via EMRs is perceived as a straightforward process with a clear, anticipated result; however, since it relies on a negotiation process among various health professionals, "digital health technologies do not ensure a favorable transformation in the health sector, as invisible labor is perpetually required for coordination and information dissemination" [2]. This "invisible labor" is diligently performed by healthcare professionals. The presence of proficient health staff capable of effective communication and information dissemination is crucial in the delivery of health services [26-28]. In a multidisciplinary healthcare team, proficient communication and collaboration skills, alongside effective coordination, are essential to avert redundancy and inconsistency in patient care, mitigate the financial strain caused by poor communication, and enhance operational efficiency, quality of care, job satisfaction, and patient safety [29-32]. Healthcare workers must interact successfully, share their expertise, and maintain open communication to function as a cohesive team [33]. Effective communication skills are essential for improving communication and coordination, resolving disputes, establishing problem-solving techniques, strengthening the performance of healthcare professionals, and contributing to the efficacy of care services [34-37].

Ensuring continuity in healthcare services and enhancing the clinical decision-making process necessitates prompt access to precise and enough data/information [16,23,28]. Currently, EMR enhances communication and the exchange of medical information among healthcare workers, particularly pharmacists, by providing enhanced communication, increased accessibility, and support for excellent treatment [12,31,38,39]. It enhances collaborative chances for obtaining essential healthcare data/information, diminishes the probability of adverse occurrences, and correlates with reduced morbidity levels [9]. Healthcare professionals experiencing communication and information overload may utilize wearable technologies and electronic medical records (EMRs) to enhance patient care, and their engagement with EMRs may alleviate the need for additional efforts to complete their responsibilities [40]. Utilizing EMR enhances the clarity of clinical notes and prompts, accelerates information interchange, enables immediate viewing, and provides access to essential data, so augmenting the visibility of diagnoses, procedures, and test results, while promoting knowledge transfer [41].

The adoption of electronic medical records (EMRs) is increasingly prevalent, despite claims that they prolong the time physicians dedicate to documentation, thereby diminishing their interaction with patients and nurses [42,43]. Additionally, EMRs may hinder direct communication between physicians and nurses, elevate the risk of incomplete and fragmented exchanges by limiting opportunities for verification, collaborative problem-solving, and clarification essential for effective communication, and potentially compromise "patient ownership." Notwithstanding these concerns, the use of EMR is swiftly escalating owing to its benefits [44-46].

Despite the abundance of literature on the general and specialized applications of EMRs, along with their associated benefits and drawbacks, there is a scarcity of research explicitly examining their impact on CSI behavior among healthcare professionals [9,31,44,47]. To enhance the efficacy of EMR use in healthcare services, it is essential to understand the obstacles encountered by health professionals in using EMRs. This research was conducted as a field investigation to ascertain the correlation between the views of pharmacists and nurses, the principal creators and consumers of medical records, regarding Electronic Medical Records (EMR) and Clinical Safety indicators (CSI) behaviors. The study is significant for elucidating the impact of EMR use on CSI behavior among healthcare workers by disclosing existing practices, hence informing future research.

## **2. The Significance of EMR in the Digital Healthcare System**

The rising utilization of Electronic Medical Records (EMR) coincides with the regulation of administrative and legal frameworks alongside advancements in digital healthcare systems, as well as a growing focus on the confidentiality, integrity, and accessibility of medical records [47,48]. Additionally, the disposition of healthcare professionals towards EMR significantly influences its adoption. The current research shows that pharmacists were more inclined to use EMR than nurses. Given that paper forms continue to be used in healthcare service delivery, it is reasonable for nurses to exhibit a more restricted engagement with electronic

medical records in their daily routines. Pharmacists had more favorable opinions toward EMRs; nonetheless, both professional groups expressed concerns about access to sufficient, trustworthy, comprehensible, and current information on EMRs. The infrequent use of EMR by nurses was attributed to their attitude towards EMR and a preference for printed forms for medical recordkeeping, which were deemed adequate. It is believed that the use of EMR will become prevalent with the incorporation of electronic care plans into the HIS and the implementation of standardized care protocols within the institution [39]. Consequently, it was determined that the use of EMR is associated not only with the hospital's present operations but also with the perceptions and attitudes of healthcare professionals toward HIS and EMR [40].

Concerns regarding the security and privacy of personal data, along with skepticism about electronic medical records (EMRs), diminish the motivation to use EMRs [41,42]. As the use of electronic medical records (EMR) grows prevalent, apprehensions about the potential harm caused by damaged, erased, or lost information—serving as administrative and legal evidence—are increasing [18]. The findings indicated that both professional groups exhibited little consensus about the trustworthiness of Electronic Medical Records (EMR), which serve as a legal safeguard by documenting treatment and care services to protect personal data privacy, as well as on the efficacy of the Health Information System (HIS). The link between personal data privacy, excluding individual and improper uses, and the HIS is directly proportional since personal data privacy is mostly a technological problem inside the HIS. The proportion of pharmacists and nurses seeing HIS as effective was below average, whereas faculty members prioritizing record security and personal data protection had higher unfavorable sentiments. Despite the increasing evidence that deep learning-based identity concealment techniques may perform well in data sharing across inter-organizational contexts, the challenges encountered by professionals in practice foster ongoing skepticism towards the Health Information System (HIS) [43]. As confidence in Health Information Systems (HIS) grows with advancements in digital healthcare, trust in Electronic Medical Records (EMR) about the safeguarding of personal data and its use will similarly rise.

Advancements in information and communication technology, especially in database systems, the internet, and communication technologies, have prompted a shift in health care in Türkiye. The intimate relationship between digital healthcare services and information and communication technology necessitates that healthcare workers possess a certain degree of technical proficiency to use these systems effectively. Insufficient technical proficiency among healthcare personnel is a barrier to the use of Electronic Medical Records (EMR) and confidence in Health Information Systems (HIS) [9,44]. Not all healthcare providers possess similar proficiency in using the tools provided by digital healthcare systems [41]. Certain organizations may oppose the shift to digital technology by refraining from its use and restricting its application [2]. This predicament, anticipated owing to the structure and workload of healthcare staff, remains an institutional challenge that must be addressed following the evolving digital healthcare services.

The current research on CSI behavior among healthcare professionals revealed that, although there was no significant difference in communication rates between pharmacists and nurses overall, the items with elevated involvement rates varied. In contrast to the results of Karadağ et al., the participation rate of pharmacists on items reflecting communication among health professionals exceeded that of nurses [35]. Erjavec et al. indicated that the frequency of pharmacists' interactions with other healthcare professionals was elevated [45]. Compelling data indicates that healthcare workers in a hospital environment allocate a substantial amount of their time to the exchange of information, namely communication [29]. While both professional groups are receptive to communication on medical information exchange and collaboration, it is significant that pharmacists exhibit more caution in disseminating medical information. Reports indicate that variations in the use of EMR regarding scope and structure influence the collaborative interactions between pharmacists and nurses, and the correlation between EMR usage and care service coordination is contingent upon the degree of cohesion among team members [46, 47]. The use of EMR proved to be a successful method for eliminating communication obstacles and enhancing information transmission between pharmacists and nurses. Cost-effective hardware, adaptable software, and an atmosphere that progressively appreciates the efficiencies provided by computers are fostering the advancement of systems for various healthcare situations [48].

The management of EMR must be meticulous to enhance its efficacy in healthcare services and its positive impact on CSI [31]. EMR facilitates communication among team members in the provision of healthcare services necessitating collaborative effort. The development of EMR, like many other domains within DHS, must fulfill several expectations about communication among healthcare professionals. The anticipated efficacy of EMR in communication is expected to rise when these predictions are fulfilled. The rising reliance on EMR for consultations, a vital communication technique among pharmacists, underscores its expanding significance in healthcare communication.

### **3. Constraints**

Given that this research was performed at a singular healthcare facility, the correlation between EMR use and CSI behavior may vary in alternative environments. This research focused only on pharmacists and nurses; nevertheless, it is essential to assess the attitudes and practices of other healthcare workers in this domain. A further constraint is the use of a printed questionnaire form in the investigation. Additional variables not included in the questionnaire or unarticulated by individuals may further influence EMR use and CSI behavior.

Notwithstanding these constraints, the current research is significant as its results illuminate pharmacists' and nurses' overall views regarding EMR, the frequency of EMR use in everyday activities, and CSI practices. This research underscores the growing significance of EMR within the digital healthcare framework and enhances the literature by elucidating the influence of EMR on CSI behavior. Determining the factors influencing health professionals' choices for

record types may provide significant insights for enhancing the adoption of digital healthcare systems.

#### **4. Conclusions**

EMR establishes a complete network by enabling communication, cooperation, and the exchange of medical information among healthcare providers via the systematic integration of patient data, allowing instantaneous access regardless of time and location. The impact of EMRs on CSI behavior was determined to be minimal; nevertheless, the use of EMRs effectively enhances CSI behaviors. EMR may remove obstacles to obtaining health records and enhance communication among health providers; it also has the potential to promote CSI behavior among them.

Electronic Medical Records (EMR) are favored and often used by doctors and nurses for executing everyday responsibilities inside healthcare institutions. Physicians have a greater frequency of EMR use and possess more positive opinions about EMR compared to nurses. A positive and strong correlation exists between EMR use and CSI activity, with EMR usage fostering CSI conduct. Physicians, who depend heavily on information for delivering health services, encounter greater challenges regarding information access, privacy, and technical support; whereas nurses, tasked with the creation of medical records, experience difficulties in record creation and preservation.

Findings reveal that the amount of technology adoption is a significant factor influencing EMR usage and CSI behavior. Alongside the procurement of the necessary software and hardware to enhance EMR use in hospitals, it is believed that training would be beneficial in promoting technology adoption among healthcare staff and mitigating the current opposition among them. While paper records cannot be entirely eradicated, the use of EMRs by nurses may be enhanced by promoting the generation of medical records in electronic format that need nurses' input and their application in collaborative efforts. The advancement of Health Information Systems (HIS) would enhance trust in Electronic Medical Records (EMRs) regarding the electronic creation of health data and the safeguarding of personal information, while also improving communication among healthcare providers.

### استخدام ملاحظات التمرريض والصيدلة في السجلات الطبية الإلكترونية لتوقع نتائج المرضى: مراجعة الملخص

**الخلفية:** أدى دمج السجلات الطبية الإلكترونية (EMRs) في أنظمة الرعاية الصحية إلى إحداث ثورة في إدارة معلومات المرضى، مما عزز الكفاءة وسهولة الوصول إلى البيانات. تستكشف هذه الدراسة تأثير السجلات الطبية الإلكترونية على سلوك مؤشر السلامة السريرية (CSI) بين المهنيين الصحيين، مع التركيز على الأطباء والمرضى الذين يلعبون أدوارًا حيوية في إنشاء واستخدام السجلات الطبية.

**الطرق:** تم إجراء مراجعة شاملة للأدبيات لتقييم مدى انتشار استخدام السجلات الطبية الإلكترونية، والفوائد المتصورة، والمخاوف، والمواقف تجاه حفظ السجلات الرقمية. تم جمع البيانات لفهم العلاقة بين اعتماد السجلات الطبية الإلكترونية والأدوار المهنية والتصورات المتعلقة بأمن البيانات وسلامتها.

**النتائج:** أظهرت النتائج ميلًا أكبر لدى الأطباء لاعتماد السجلات الطبية الإلكترونية مقارنة بالمرضى، حيث أعرب كلا الفريقين عن مخاوف مشتركة بشأن سهولة الوصول إلى البيانات وموثوقيتها وفهمها. وُجد أن المرضى يميلون إلى تفضيل السجلات الورقية التقليدية، مما يؤثر على مشاركتهم في استخدام السجلات الطبية الإلكترونية. تم تسليط الضوء على مخاوف تتعلق بأمن وخصوصية البيانات المحفوظة في السجلات الطبية الإلكترونية، مما أثر على ثقة المهنيين في نظم المعلومات الصحية (HIS) وضمانات الخصوصية.

**الاستنتاج:** تؤكد الدراسة على أهمية معالجة مواقف المهنيين الصحيين ومخاوفهم تجاه السجلات الطبية الإلكترونية لتعزيز تكاملها واستخدامها. التدريب المحسن على الأنظمة الصحية الرقمية ومعالجة قضايا أمن البيانات أمران أساسيان لتعزيز اعتماد السجلات الطبية الإلكترونية وضمان التواصل الفعال والتعاون بين فرق الرعاية الصحية. ينبغي أن تركز الأبحاث المستقبلية على تقليل الحواجز أمام استخدام السجلات الطبية الإلكترونية وتعزيز الثقة في تقنيات الرعاية الصحية الرقمية.

**الكلمات المفتاحية:** السجلات الطبية الإلكترونية، مؤشرات السلامة السريرية، المهنيون الصحيون، أمن البيانات، الرعاية الصحية الرقمية.
